# ABSTRACT

An infant carrier is shown that can be used as a rearwardly facing infant car seat either by itself or attached to a separate base support, as a stroller seat, or as a carrier for an infant with an adjustable handle attached between longitudinally opposed ends of the carrier. The separate base support can be belted into a vehicle seat and left in place after the infant carrier is removed. The base support has a vertical portion that rests parallel to the back seat of the vehicle and includes a mirror mounted high enough on the back portion to be visible from the vehicle's rear view mirror when the infant carrier is mounted in the base support. The infant carrier has a handle that can be reciprocated in the axial direction of the carrier to actuate two separate attachment mechanisms for attaching the infant carrier to the base support or to a stroller.
